Purpose

Grocery Shop Management System is based on a concept of making grocery orders from customers to providers. The purpose of this system is basically connect the providers and customers in a large platform where provider can increase their sell so fast and customers can buy their desire product from home which will also consume time and make the life easier. On a web-based marketplace, each small business receives a greater exposure, than when operating alone, which in turn provides a greater opportunity for increased sales. Besides, customers also wants many option before buying any product and want to order from home. So eventually, providers can reach to the bigger number of customers and customers can reach to a big number of grocery shops as well through this platform instantly from anywhere.

Intended Audience and Reading Suggestions

- Providers
- Customers

Intended Use

This website is intended for the customer who are willing to buy product through online want many alternatives and want to save their time as well. Also for the providers who have grocery shop and who are willing to increase their sale or gain more market exposure. The rest of the SRS contains every details required for the software to work effectively.

Product Scope

Grocery Shop Management System is a single platform for different grocery shops to enhance their sale. Different grocery shop will offer their products. In this application the customer can login, select products, quantity and proceed towards confirm order. After confirming the order grocery provider will get a notification of order and he will start going to customers location with the grocery container(vehicle). Payment method will be cash on delivery. This website will give the companies a greater exposure to their products.

References

- https://en.wikipedia.org/wiki/Software_requirements
- https://wiki2.org/en/Software_requirements
- <https://evolpe.com/wiki-srs/>

Product Perspective

There will be three types of users in the system there are Admins, Shop owners and customers. First of all, the admin will have control and knowledge over the entire system. They can directly monitor the customer's tasks and shipowner's tasks and also approve requests and products. They can add and remove products as well. The shop owner got access to the shop information and has privilege to update it as well. The shop owner will be able to see shops current order request and can accept and cancel the request and also, they can see all order done information. Along with ordering food stuff online, the customers can view their personal information and update it in need. They can view which orders are pending and which are received.

Product Functions

We are basically building this system in order to help people do online grocery shopping without needing to go out for shopping in this corona pandemic which is going to be fast and affordable. In the recent time in online shopping systems it takes a lot of time delivering the order to the customer as a certain delivery man goes to the shop then buy stuff and then finally deliver it which seems like a long process and requires quite a lot of time, Therefore, we have built a fast and affordable portable online shopping system where a vehicle with groceries will be there in all over the residential area by which the customers can get their ordered items faster than ever as the vehicle which is like a shop itself will reach the spot directly. Well first of all, Customers should need the information before they consume anything from the system. Our Web-application shall contain detailed information about the product, price, availability, physical shop Address.

Searching Shop: Customer can search nearer available shop by giving location can Gate all details of the shop with product availability. Give Orders: Then using nearer shop personal id with product list customer can give Order. Customer info: Customer can see his personal info. Order received: Till now received order of that customer will be shown. Order running: Till now running order will be shown once the order has done then automatically the order will be shift on received order. Update Info: Customer can update his/her info. Logout: Customer can log out.

Operating environment for the online grocery shopping is listed below:

- Distributed database: MySQL.
- Operating system: Windows/ Linux/ MAC.
- Back-end: Php.
- Front-end: HTML, CSS, JavaScript.

Design and Implementation Constraints

The user needs to log in/register first with an personal email and password of their own. A computer or a smart phone device will be needed to access the site.

Assumptions and Dependencies

As online grocery shopping will be a web based platform, so a good internet connection will be

required to access the website. It will be assumed that the users will possess good internet connectivity. Also, it is assumed that the user is familiar with the usage of smartphone as smart phone access will be needed. Users will have to register using email address, so it is assumed that the will have one. The user interface will be in Basic English, so it is assumed that the user will have basic knowledge of English.

External Interface Requirements

Product CRUD

Description Enabling the shop owners to add product to the platform is an essential function of the software. While doing so they should be given the opportunity to update and delete their products if necessary. That's why we need a CRUD operation on the product entity.

Product Search

There will be a search function in the homepage, where the user can search his desired product and shop, he wants to look at. The search function will take the input from user and filter out the product or shop and will view it to the user. Similar product to the searched product will be also shown. If any product is not available than the page will pop out "Product not found" or "Shop not found". Customer can give review after shopping.

Shop search

Description Customer can search nearer shop through searching with location then can get all the information of the shop.

Product Update

Description Shop owner can update his information including product stock with price at any time.

Operations

- Add Product
- Remove Product
- Update Quantity.

3.1.1 Customer Verification

Description When to register as customer first, the customer register and can get access after within some seconds by admin. Whenever any transaction is going to take place involving this website, the shop owners must verify the customer. If the customer is not verified, there can be fraud usage.

Operation

The shop owner will search for the customer profile. After finding them profile, the shop owner will send a verification email or number to the customers contact number or email. As soon as the customer is verified, the transaction can be completed.

Stimulus/Response Sequences

Both user customer/shop owner can get the order running, order done of their profile at a time

and get the response instant

User Interfaces

The user interface will be punchy and attractive. The user interface will be simple and intuitive so that anyone can easily understand and use it.

Hardware Interfaces

Laptop/Desktop PC for accessing the App.

Printer to print invoice.

Wi-fi to connect internet.

Software Interfaces

There will be a search function in the homepage, where the user can search his desired product and shop, he wants to look at. The search function will take the input from user and filter out the product or shop and will view it to the user. Similar product to the searched product will be also shown. If any product is not available then the page will pop out "Product not found" or "Shop not found". Customer can give review after shopping.

Security Requirements

Security requirements of the system:

1. Encrypt users' private information
2. Encrypt payment information
3. Showing the right content to the right audience.

Ethical Requirements

Ethical requirements of the system:

4. Giving all shop owners equal and fair chance to promote and sell their products.
5. Giving customers their deserved amount of points.
6. Keeping customer purchase history private.

3.1.2 Performance

Based on the performance the requirements of the system:

7. Fast Response Time for User Login the average response time for user login after entering user name and password should be no more than 3 sec and the maximum response time should be 10 seconds.
8. Maximum people should be able to concurrently visit the website.

Learning Outcomes: Students should have the ability to

LO1: List various hardware and software requirements

LO2: Distinguish between functional and nonfunctional requirements

LO3: Indicate the order of priority for various requirements

LO4: Analyze the requirements for feasibility Course

Course Outcomes: Upon completion of the course students will be able to prepare SRS document

Conclusion: successfully understood SRS for project and created the same for Grocery Management System.

Experiment 2: Draw DFD (upto 2 levels) and prepare Data Dictionary for the project

Learning Objective: Students will be able to identify the data flows, processes, source and destination for the project, Analyze and design the DFD upto 2 levels, develop a data dictionary for the project

Tools: Dia, StarUML

Theory:

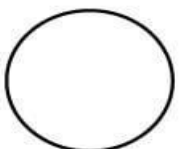

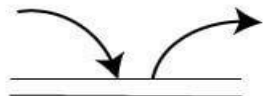

A Data Flow Diagram (DFD) is a traditional visual representation of the information flows within a system. A neat and clear DFD can depict the right amount of the system requirement graphically. It can be manual, automated, or a combination of both.

It shows how data enters and leaves the system, what changes the information, and where data is stored. The objective of a DFD is to show the scope and boundaries of a system as a whole. It may be used as a communication tool between a system analyst and any person who plays a part in the order that acts as a starting point for redesigning a system. The DFD is also called as a data flow graph or bubble chart.

The following observations about DFDs are essential:

1. All names should be unique. This makes it easier to refer to elements in the DFD.
2. Remember that DFD is not a flow chart. Arrows in a flow chart represent the order of events; arrows in DFD represent flowing data. A DFD does not involve any order of events.
3. Suppress logical decisions. If we ever have the urge to draw a diamond-shaped box in a DFD, suppress that urge! A diamond-shaped box is used in flow charts to represent decision points with multiple existing paths of which the only one is taken. This implies an ordering of events, which makes no sense in a DFD.
4. Do not become bogged down with details. Defer error conditions and error handling until the end of the analysis.

Standard symbols for DFDs are derived from the electric circuit diagram analysis and are shown in fig:

Symbol	Name	Function
	Data flow	Used to Connect Processes to each other, to sources or Sinks; the arrow head indicates direction of data flow.
	Process	Performs Some transformation of Input data to yield output data.
	Source of Sink (External Entity)	A Source of System inputs or Sink of System outputs.
	Data Store	A repository of data; the arrow heads indicate net inputs and net outputs to store.

Symbols for Data Flow Diagrams

Circle: A circle (bubble) shows a process that transforms data inputs into data outputs.

Data Flow: A curved line shows the flow of data into or out of a process or data store.

Data Store: A set of parallel lines shows a place for the collection of data items. A data store indicates that the data is stored which can be used at a later stage or by the other processes in a different order. The data store can have an element or group of elements.

Levels in Data Flow Diagrams (DFD)

The DFD may be used to perform a system or software at any level of abstraction. Infact, DFDs may be partitioned into levels that represent increasing information flow and functional detail. Levels in DFD are numbered 0, 1, 2 or beyond. Here, we will see primarily three levels in the data flow diagram, which are: 0-level DFD, 1-level DFD, and 2-level DFD.

0-level DFDM

It is also known as fundamental system model, or context diagram represents the entire software requirement as a single bubble with input and output data denoted by incoming and outgoing arrows. Then the system is decomposed and described as a DFD with multiple bubbles. Parts of the system represented by each of these bubbles are then decomposed and documented as more and more detailed DFDs. This process may be repeated at as many levels as necessary until the program at hand is well understood. It is essential to preserve the number of inputs and outputs between levels, this concept is called leveling by

DeMacro. Thus, if bubble "A" has two inputs x_1 and x_2 and one output y , then the expanded DFD, that represents "A" should have exactly two external inputs and one external output as shown in fig:

Fig: Level-0 DFD.

1-level DFD

In 1-level DFD, a context diagram is decomposed into multiple bubbles/processes. In this level, we highlight the main objectives of the system and breakdown the high-level process of 0-level DFD into subprocesses.

2-Level DFD

2-level DFD goes one process deeper into parts of 1-level DFD. It can be used to project or record the specific/necessary detail about the system's functioning.

Learning Outcomes: Students should have the ability to

LO1: Identify the dataflows, processes, source and destination for the project.

LO2: Analyze and design the DFD upto 2 levels

LO3: Develop a data dictionary for the project

Outcomes: Upon completion of the course students will be able to prepare Draw DFD (upto 2 levels) and prepare Data Dictionary for the project

Conclusion: successfully understood and implemented DFD for Grocery Management System.

Experiment 03- Implement UML Use-case diagram

Learning Objective: To implement UML use-case diagram for the project.

Tools: MS Word, draw.io

Theory:

Use case diagrams

Use case diagrams belong to the category of behavioral diagram of UML diagrams. Use case diagrams aim to present a graphical overview of the functionality provided by the system. It consists of a set of actions (referred to as use cases) that the concerned system can perform one or more actors, and dependencies among them.

Actor

An actor can be defined as an object or set of objects, external to the system, which interacts with the system to get some meaningful work done. Actors could be human, devices, or even other systems. For example, consider the case where a customer *withdraws cash* from an ATM. Here, customer is a human actor.

Actors can be classified as below:

- **Primary actor:** They are principal users of the system, who fulfill their goal by availing some service from the system. For example, a customer uses an ATM to withdraw cash when he needs it. A customer is the primary actor here.
- **Supporting actor:** They render some kind of service to the system. "Bank representatives", who replenishes the stock of cash, is such an example. It may be noted that replenishing stock of cash in an ATM is not the prime functionality of an ATM.

In a use case diagram primary actors are usually drawn on the top left side of the diagram.

Use Case

A use case is simply a functionality provided by a system.

Continuing with the example of the ATM, *withdraw cash* is a functionality that the ATM provides.

Therefore, this is a use case. Other possible use cases include, *check balance*, *change PIN*, and so on.

Use cases include both successful and unsuccessful scenarios of user interactions with the system. For example, authentication of a customer by the ATM would fail if he enters wrong PIN. In such case, an error message is displayed on the screen of the ATM.

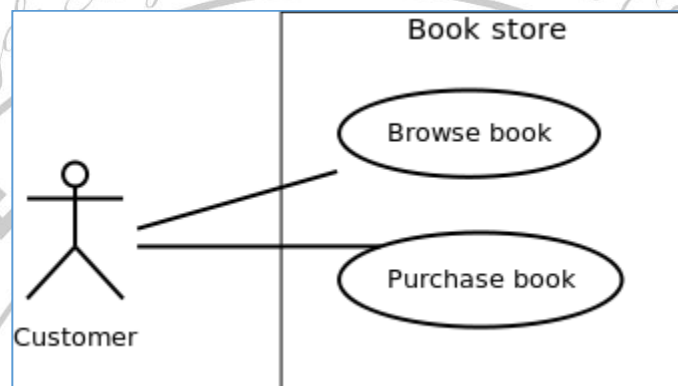

Subject

Subject is simply the system under consideration. Use cases apply to a subject. For example, an ATM is a subject, having multiple use cases, and multiple actors interact with it. However, one should be careful of external systems interacting with the subject as actors.

Graphical Representation

An actor is represented by a stick figure and name of the actor is written below it. A use case is depicted by an ellipse and name of the use case is written inside it. The subject is shown by drawing a rectangle. Label for the system could be put inside it. Use cases are drawn inside the rectangle, and actors are drawn outside the rectangle, as shown in figure - 01.

Figure - 01: A use case diagram for a book store

Association between Actors and Use Cases

A use case is triggered by an actor. Actors and use cases are connected through binary associations indicating that the two communicate through message passing.

An actor must be associated with at least one use case. Similarly, a given use case must be associated with at least one actor. Association among the actors is usually not shown. However, one can depict the class hierarchy among actors.

Use Case Relationships

Three types of relationships exist among use cases:

- Include relationship
- Extend relationship
- Use case generalization

Include Relationship

Include relationships are used to depict common behavior that are shared by multiple use cases. This could be considered analogous to writing functions in a program in order to avoid repetition of writing the same code. Such a function would be called from different points within the program.

Example

For example, consider an email application. A user can send a new mail, reply to an email he has

received, or forward an email. However, in each of these three cases, the user must be logged in to perform those actions. Thus, we could have a *login* use case, which is included by *compose mail*, *reply*, and *forward email* use cases. The relationship is shown in figure - 02.

Figure - 02: Include relationship between use cases

Notation

Include relationship is depicted by a dashed arrow with a «include» stereotype from the including use case to the included use case.

Extend Relationship

Use case extensions are used to depict any variation to an existing use case. They are used to specify the changes required when any assumption made by the existing use case becomes false.

Example

Let's consider an online bookstore. The system allows an authenticated user to buy selected book(s). While the order is being placed, the system also allows specifying any special shipping instructions, for example, call the customer before delivery. This *Shipping Instructions* step is optional, and not a part of the main *Place Order* use case. Figure - 03 depicts such relationship.

Figure - 03: Extend relationship between use cases

Notation

Extend relationship is depicted by a dashed arrow with a «extend» stereotype from the extending use case to the extended use case.

Generalization Relationship

Generalization relationship is used to represent the inheritance between use cases. A derived use case specializes some functionality it has already inherited from the base use case.

Example

To illustrate this, consider a graphical application that allows users to draw polygons. We could have a use case *draw polygon*. Now, rectangle is a particular instance of polygon having four sides at right angles to each other. So, the use case *draw rectangle* inherits the properties of the use case *draw polygon* and overrides its drawing method. This is an example of generalization relationship. Similarly, a generalization relationship exists between *draw rectangle* and *draw square* use cases. The relationship has been illustrated in figure - 04.

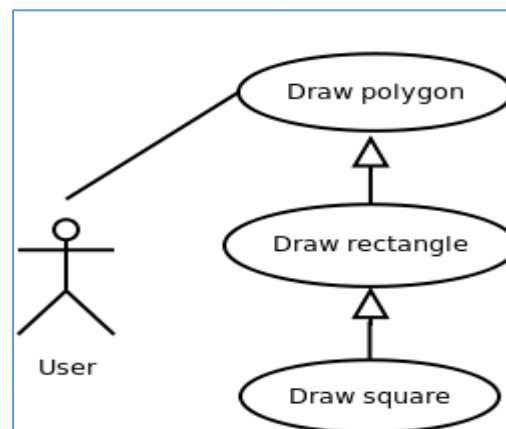

Figure - 04: Generalization relationship among use cases

Notation

Generalization relationship is depicted by a solid arrow from the specialized (derived) use case to the more generalized (base) use case.

Identifying Actors

Given a problem statement, the actors could be identified by asking the following questions :

- Who gets most of the benefits from the system? (The answer would lead to the identification of the primary actor)
- Who keeps the system working? (This will help to identify a list of potential users)
- What other software / hardware does the system interact with?
- Any interface (interaction) between the concerned system and any other system?

Procedure:

A Use Case model can be developed by following the steps below.

1. Identify the Actors (role of users) of the system.
2. For each category of users, identify all roles played by the users relevant to the system.
3. Identify what are the users required the system to be performed to achieve these goals.
4. Create use cases for every goal.
5. Structure the use cases.
6. Prioritize, review, estimate and validate the users.

Result and Discussion:

Q.1) What is a use-case diagram? Draw at least two use-cases for your projects.

Learning Outcomes: The student should have the ability to:

LO 1: Identify the importance of use-case diagrams.

LO 2: Draw use-case diagrams for a given scenario.

Course Outcomes: Upon completion of the course students will be able to understand and demonstrate use-case diagrams.

Conclusion: Thus, students have understood and successfully drawn use-case diagrams.

Viva Questions:

1. What is use-case diagrams used for?
2. Enumerate on the type of relationships that exists for use-case diagram.

For Faculty Use:

Correction Parameters	Formative Assessment [40%]	Timely completion of Practical [40%]	Attendance / Learning Attitude [20%]	
Marks Obtained				

Experiment 4- Implement UML Class Diagram

Learning Objective: To implement UML class diagram for the project.

Tools: MS Word, draw.io

Theory:

Class Diagrams:

Classes are the structural units in object oriented system design approach, so it is essential to know all the relationships that exist between the classes, in a system. All objects in a system are also interacting to each other by means of passing messages from one object to another.

Elements in class diagram

Class diagram contains the system classes with its data members, operations and relationships between classes.

Class

A set of objects containing similar data members and member functions is described by a class. In UML syntax, class is identified by solid outline rectangle with three compartments which contain

- **Class name**

A class is uniquely identified in a system by its name. A textual string [2] is taken as class name. It lies in the first compartment in class rectangle.

- **Attributes**

Property shared by all instances of a class. It lies in the second compartment in class rectangle.

- **Operations**

An execution of an action can be performed for any object of a class. It lies in the last compartment in class rectangle.

Example

To build a structural model for an Educational Organization, 'Course' can be treated as a class which contains attributes 'courseName' & 'courseID' with the operations 'addCourse()' & 'removeCourse()' allowed to be performed for any object to that class.

- **Generalization/Specialization**

It describes how one class is derived from another class. Derived class inherits the properties of its parent class.

Example

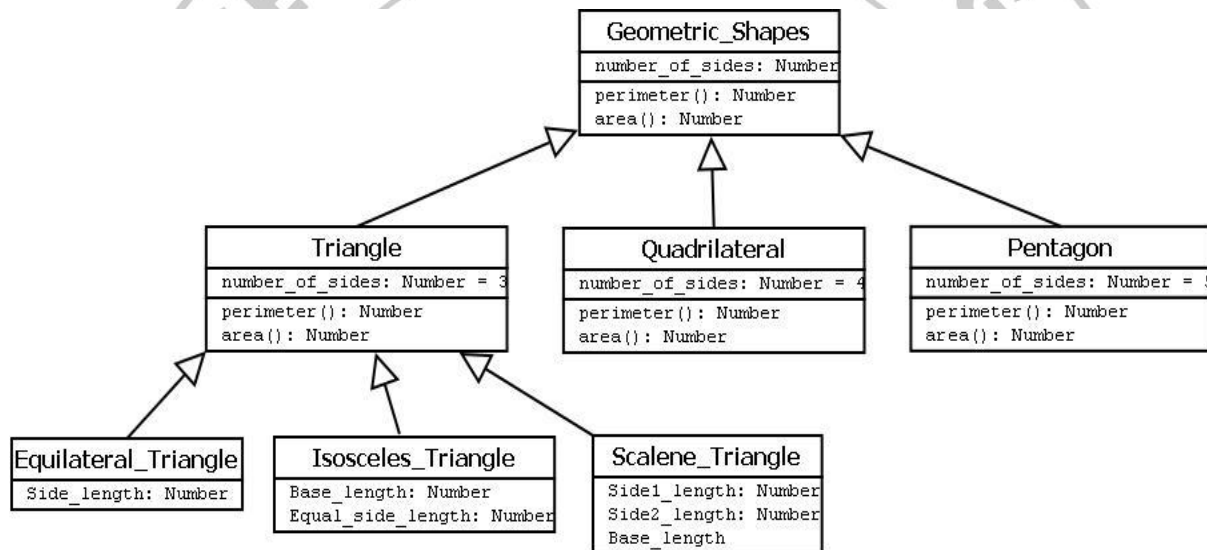

Figure-02:

Geometric_Shapes is the class that describes how many sides a particular shape has. Triangle, Quadrilateral and Pentagon are the classes that inherit the property of the Geometric_Shapes class. So the relations among these classes are generalization. Now Equilateral_Triangle, Isosceles_Triangle and Scalene_Triangle, all these three classes inherit the properties of Triangle class as each one of them has three sides. So, these are specialization of Triangle class.

Relationships

Existing relationships in a system describe legitimate connections between the classes in that system.

- **Association**

It is an instance level relationship that allows exchanging messages among the objects of both ends of association. A simple straight line connecting two class boxes represent an association. We can give a name to association and also at the both end we may indicate role names and multiplicity of the adjacent classes. Association may be uni-directional.

Example

In structure model for a system of an organization an employee (instance of 'Employee' class) is always assigned to a particular department (instance of 'Department' class) and the association can be shown by a line connecting the respective classes.

Figure-03:

- **Aggregation**

It is a special form of association which describes a part-whole relationship between a pair of classes. It means, in a relationship, when a class holds some instances of related class, then that relationship can be designed as an aggregation.

Example

For a supermarket in a city, each branch runs some of the departments they have. So, the relation among the classes 'Branch' and 'Department' can be designed as aggregation. In UML, it can be shown as in the fig. below.

Figure-04:

- **Composition**

It is a strong form of aggregation which describes that whole is completely owns its part. Life cycle of the part depends on the whole.

Example

Let consider a shopping mall has several branches in different locations in a city. The existence of branches completely depends on the shopping mall as if it is not exist any branch of it will no longer exists in the city. This relation can be described as composition and can be shown as below

Figure-05:

- **Multiplicity**

It describes how many numbers of instances of one class is related to the number of instances of another class in an association.

Notation for different types of multiplicity:

Single instance	1
Zero or one instance	0..1
Zero or more instance	0..*
One or more instance	1..*
Particular range(two to six)	2..6

Figure-06:

Example

One vehicle may have two or more wheels

Figure-07:

Procedure:

When required to describe the static view of a system or its functionalities, we would be required to draw a class diagram. Here are the steps you need to follow to create a class diagram.

Step 1: Identify the class names

The first step is to identify the primary objects of the system.

Step 2: Distinguish relationships

Next step is to determine how each of the classes or objects are related to one another. Look out for commonalities and abstractions among them; this will help you when grouping them when drawing the class diagram.

Step 3: Create the Structure

First, add the class names and link them with the appropriate connectors. You can add attributes and functions/ methods/ operations later.

Result and Discussion:

Q.1) What is a class diagram? Draw at least two class diagram for your projects.

Learning Outcomes: The student should have the ability to:

LO 1: Identify the importance of class diagrams.

LO 2: Draw class diagrams for a given scenario.

Course Outcomes: Upon completion of the course students will be able to understand and demonstrate class diagrams.

Conclusion: Thus, students have understood and successfully drawn class diagrams.

Viva Questions:

1. What is a class diagrams used for?
2. Enumerate various relationships in a class diagram.

For Faculty Use:

Correction Parameters	Formative Assessment [40%]	Timely completion of Practical [40%]	Attendance / Learning Attitude [20%]	
Marks Obtained				

Experiment 5- Implement State/Activity diagrams

Learning Objective: To implement dynamic view of a system using Activity/State diagrams.

Tools: MS Word, draw.io

Theory:

Capturing the dynamic view of a system is very important for a developer to develop the logic for a system. State chart diagrams and activity diagrams are two popular UML diagram to visualize the dynamic behavior of an information system.

In this experiment, we will learn about the different components of activity diagram and state chart diagram and how these can be used to represent the dynamic nature of an information system.

State-chart Diagrams

In case of Object Oriented Analysis and Design, a system is often abstracted by one or more classes with some well defined behavior and states. A *state chart diagram* is a pictorial representation of such a system, with all its states, and different events that lead transition from one state to another.

To illustrate this, consider a computer. Some possible states that it could have are: running, shutdown, hibernate. A transition from running state to shutdown state occur when user presses the "Power off" switch, or clicks on the "Shut down" button as displayed by the OS. Here, clicking on the shutdown button, or pressing the power off switch act as external events causing the transition.

State-chart diagrams are normally drawn to model the behavior of a complex system. For simple systems this is optional.

Building Blocks of a State-chart Diagram

State

A state is any "distinct" stage that an object (system) passes through in it's lifetime. An object remains in a given state for finite time until "something" happens, which makes it to move to another state. All such states can be broadly categorized into following three types:

- Initial: The state in which an object remain when created
- Final: The state from which an object do not move to any other state [optional]
- Intermediate: Any state, which is neither initial, nor final

As shown in figure-01, an initial state is represented by a circle filled with black. An intermediate state is depicted by a rectangle with rounded corners. A final state is represented by a unfilled circle with an inner black-filled circle.

Figure-01: Representation of initial, intermediate, and final states of a state chart diagram

Intermediate states usually have two compartments, separated by a horizontal line, called the name compartment and internal transitions compartment. They are described below:

- Name compartment: Contains the name of the state, which is a short, simple, descriptive string
- Internal transitions compartment: Contains a list of internal activities performed as long as the system is in this state

The internal activities are indicated using the following syntax: action-label / action-expression. Action labels could be any condition indicator. There are, however, four special action labels:

- Entry: Indicates activity performed when the system enter this state
- Exit: Indicates activity performed when the system exits this state
- Do: indicate any activity that is performed while the system remain in this state or until the action expression results in a completed computation
- Include: Indicates invocation of a sub-machine

Any other action label identifies the event (internal transition) as a result of which the corresponding action is triggered. Internal transition is almost similar to self transition, except that the former doesn't result in execution of entry and exit actions. That is, system doesn't exit or re-enter that state. Figure-02 shows the syntax for representing a typical (intermediate) state

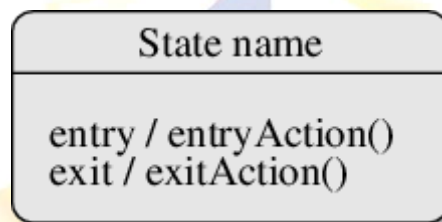

Figure-02: A typical state in a state chart diagram

States could again be either simple or composite. Here, however, we will deal only with simple states.

Transition

Transition is movement from one state to another state in response to an external stimulus (or any internal event). A transition is represented by a solid arrow from the current state to the next state. It is labeled by: event [guard-condition]/[action-expression], where

- Event is the what is causing the concerned transition (mandatory) -- Written in past tense
- Guard-condition is (are) precondition(s), which must be true for the transition to happen
- Action-expression indicate action(s) to be performed as a result of the transition

It may be noted that if a transition is triggered with one or more guard-condition(s), which evaluate to false, the system will continue to stay in the present state. Also, not all transitions do result in a state

change. For example, if a queue is full, any further attempt to append will fail until the delete method is invoked at least once. Thus, state of the queue doesn't change in this duration.

Action

An action represents behavior of the system. While the system is performing any action for the current event, it doesn't accept or process any new event. The order, in which different actions are executed, is given below:

1. Exit actions of the present state
2. Actions specified for the transition
3. Entry actions of the next state

Activity Diagrams

Activity diagrams fall under the category of behavioral diagrams in Unified Modeling Language. It is a high level diagram used to visually represent the flow of control in a system. It has similarities with traditional flow charts. However, it is more powerful than a simple flow chart since it can represent various other concepts like concurrent activities, their joining, and so on.

Activity diagrams, however, cannot depict the message passing among related objects. As such, it can't be directly translated into code. These kinds of diagrams are suitable for confirming the logic to be implemented with the business users. These diagrams are typically used when the business logic is complex. In simple scenarios it can be avoided entirely.

Components of an Activity Diagram

Below we describe the building blocks of an activity diagram.

Activity

An activity denotes a particular action taken in the logical flow of control. This could simply be invocation of a mathematical function, alter an object's properties and so on. An activity is represented with a rounded rectangle, as shown in table-01. A label inside the rectangle identifies the corresponding activity.

There are two special types of activity nodes: initial and final. They are represented with a filled circle, and a filled in circle with a border respectively (table-01). Initial node represents the starting point of a flow in an activity diagram. There could be multiple initial nodes, which mean that invoking that particular activity diagram would initiate multiple flows.

A final node represents the end point of all activities. Like an initial node, there could be multiple final nodes. Any transition reaching a final node would stop all activities.

Flow

A flow (also termed as edge or transition) is represented with a directed arrow. This is used to depict transfer of control from one activity to another, or to other types of components, as we will see below. A flow is often accompanied with a label, called the guard condition, indicating the necessary condition for the transition to happen. The syntax to depict it is [guard condition].

Decision

A decision node, represented with a diamond, is a point where a single flow enters and two or more flows leave. The control flow can follow only one of the outgoing paths. The outgoing edges often have guard conditions indicating true-false or if-then-else conditions. However, they can be omitted in obvious cases. The input edge could also have guard conditions. Alternately, a note can be attached to the decision node indicating the condition to be tested.

Merge

This is represented with a diamond shape, with two or more flows entering, and a single flow leaving out. A merge node represents the point where at least a single control should reach before further processing could continue.

Fork

Fork is a point where parallel activities begin. For example, when a student has been registered with a college, he can in parallel apply for student ID card and library card. A fork is graphically depicted with a black bar, with a single flow entering and multiple flows leaving out.

Join

A join is depicted with a black bar, with multiple input flows, but a single output flow. Physically it represents the synchronization of all concurrent activities. Unlike a merge, in case of a join all of the incoming controls **must be completed** before any further progress could be made. For example, a sales order is closed only when the customer has received the product, **and** the sales company has received its payment.

Note

UML allows attaching a note to different components of a diagram to present some textual information. The information could simply be a comment or may be some constraint. A note can be attached to a decision point, for example, to indicate the branching criteria.

Partition

Different components of an activity diagram can be logically grouped into different areas, called partitions or swim lanes. They often correspond to different units of an organization or different actors. The drawing area can be partitioned into multiple compartments using vertical (or horizontal) parallel lines. Partitions in an activity diagram are not mandatory. The following table shows commonly used components with a typical activity diagram.

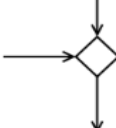

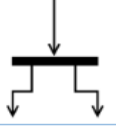

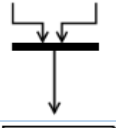

Component	Graphical Notation
Activity	An Activity
Flow	[A Flow]
Decision	
Merge	
Fork	
Join	
Note	A simple note

Table-01: Typical components used in an activity diagram

A Simple Example

Figure-04 shows a simple activity diagram with two activities. The figure depicts two stages of a form submission. At first a form is filled up with relevant and correct information. Once it is verified that there is no error in the form, it is then submitted. The two other symbols shown in the figure are the initial node (dark filled circle), and final node (outer hollow circle with inner filled circle). It may be noted that there could be zero or more final node(s) in an activity diagram.

Figure-04: A simple activity diagram.

Procedure:

Guidelines for drawing State chart Diagrams

Following steps could be followed, to draw a state chart diagram:

- For the system to developed, identify the distinct states that it passes through
- Identify the events (and any precondition) that cause the state transitions. Often these would be the methods of a class as identified in a class diagram.
- Identify what activities are performed while the system remains in a given state

Result and Discussion:

Q.1) what is a dynamic view of a system? Draw at least one state diagram and one activity diagram for your mini project.

Learning Outcomes: The student should have the ability to:

LO 1: Identify the importance of state diagram.

LO 2: Draw activity diagrams for a given scenario.

Course Outcomes: Upon completion of the course students will be able to understand and demonstrate state and activity diagrams.

Conclusion: Thus, students have understood and successfully drawn state and activity diagrams.

Viva Questions:

1. What is a state diagram used for?
2. Enumerate the steps to draw an activity diagram.

For Faculty Use:

Experiment 6: Sketch Sequence and Collaboration diagram for the project

Learning Objective: Students will able to draw Sequence and Collaboration diagram for the project

Tools: Dia, StarUML

Theory:

A sequence diagram shows, as parallel vertical lines (*lifelines*), different processes or objects that live simultaneously, and, as horizontal arrows, the messages exchanged between them, in the order in which they occur. This allows the specification of simple runtime scenarios in a graphical manner.

Sequence Diagram representation

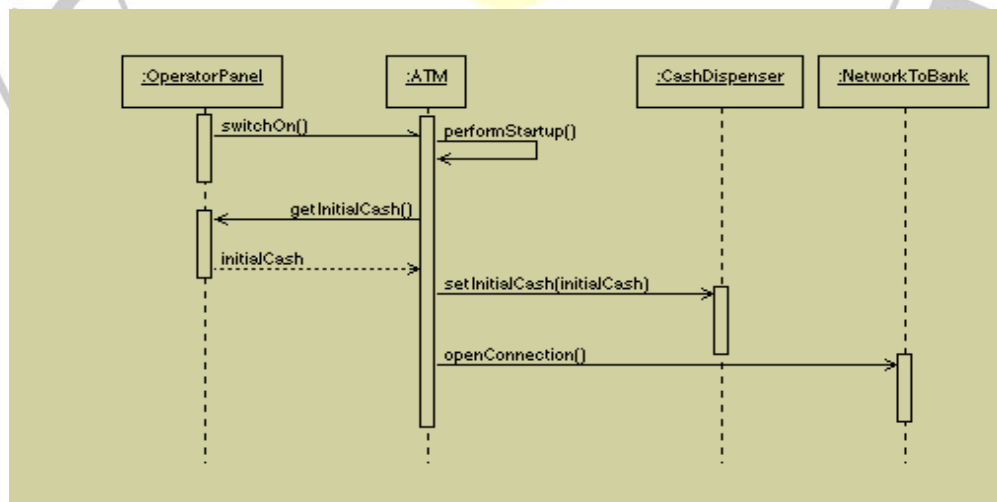

Call Message: A message defines a particular communication between Lifelines of an Interaction.

Destroy Message: Destroy message is a kind of message that represents the request of destroying the lifecycle of target lifeline.

LifeLine: A lifeline represents an individual participant in the Interaction.

Recursive Message: Recursive message is a kind of message that represents the invocation of message of the same lifeline. It's target points to an activation on top of the activation where the message was invoked from.

Sequence Diagram: Example for ATM System startup

Collaboration diagram for ATM System startup

It is clear that sequence charts have a number of very powerful advantages. They clearly depict the sequence of events, show when objects are created and destroyed, are excellent at depicting concurrent operations, and are invaluable for hunting down race conditions. However, with all their advantages, they are not perfect tools. They take up a lot of space, and do not present the interrelationships between the collaborating objects very well. A collaboration diagram, also known as a communication diagram, depicts the relationships and interactions among software objects in the UML diagrams. Collaboration diagrams are best suited to the portrayal of simple interactions among relatively small numbers of objects. Collaboration diagrams are used to visualize the structural organization of objects and their interactions. Sequence diagrams, focus on the order of messages that flow between objects.

Learning Outcomes: Students should have the ability to

- LO1: Identify the classes and objects.
- LO2: Identify the interactions between the objects
- LO3: Develop a sequence diagram for different scenarios
- LO4: generate the collaboration diagram

Outcomes: Upon completion of the course students will be able to draw the sequence and collaboration diagram for the project.

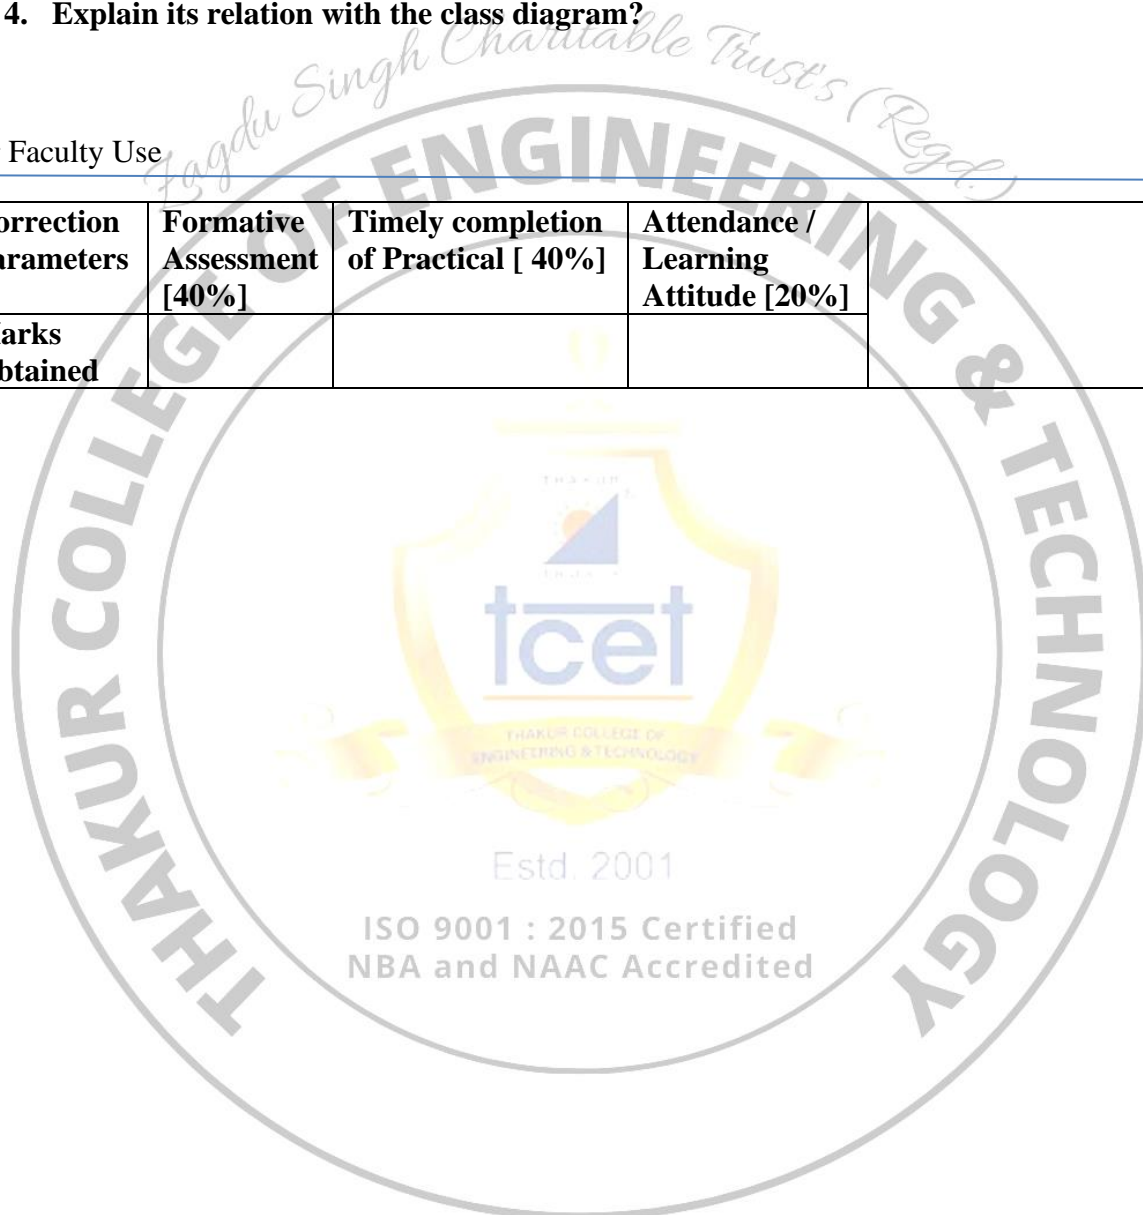

Conclusion: successfully implemented and understood sequence and collaboration diagram for Grocery management system.

Viva Questions:

1. What is a sequence diagram
2. Difference between sequence and collaboration diagram?
3. What are entities in sequence diagram?
4. Explain its relation with the class diagram?

For Faculty Use

Correction Parameters	Formative Assessment [40%]	Timely completion of Practical [40%]	Attendance / Learning Attitude [20%]	
Marks Obtained				

Experiment 7: Use project management tool to prepare schedule for the project.

Learning Objective: Students will be able to List the various activities in the project, analyze the various activities for schedule, estimate the time for each activity and develop a Gantt Chart for the activities.

Tools: Gantt Chart using MSEXcel

Theory:

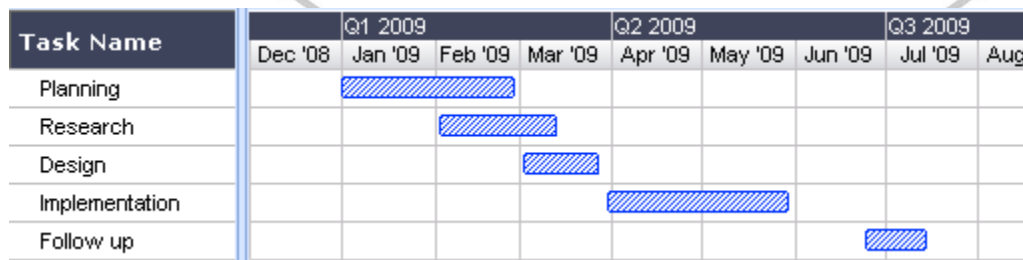

The main aim of PROJECT SCHEDULING AND TRACKING is to get the project completed on time. Program evaluation and review technique (PERT) and Gantt chart are two project scheduling methods that can be applied to software development

Split the project into tasks and estimate time and resources required to complete each task. Organize tasks concurrently to make optimal use of workforce. Minimize task dependencies to avoid delays caused by one task waiting for another to complete.

Gantt chart:

A Gantt chart, commonly used in project management, is one of the most popular and useful ways of showing activities (tasks or events) displayed against time. On the left of the chart is a list of the activities and along the top is a suitable time scale. Each activity is represented by a bar; the position and length of the bar reflects the start date, duration and end date of the activity. This allows you to see at a glance:

- What the various activities are
- When each activity begins and ends
- How long each activity is scheduled to last
- Where activities overlap with other activities, and by how much
- The start and end date of the whole project

Learning Outcomes: Students should have the ability to

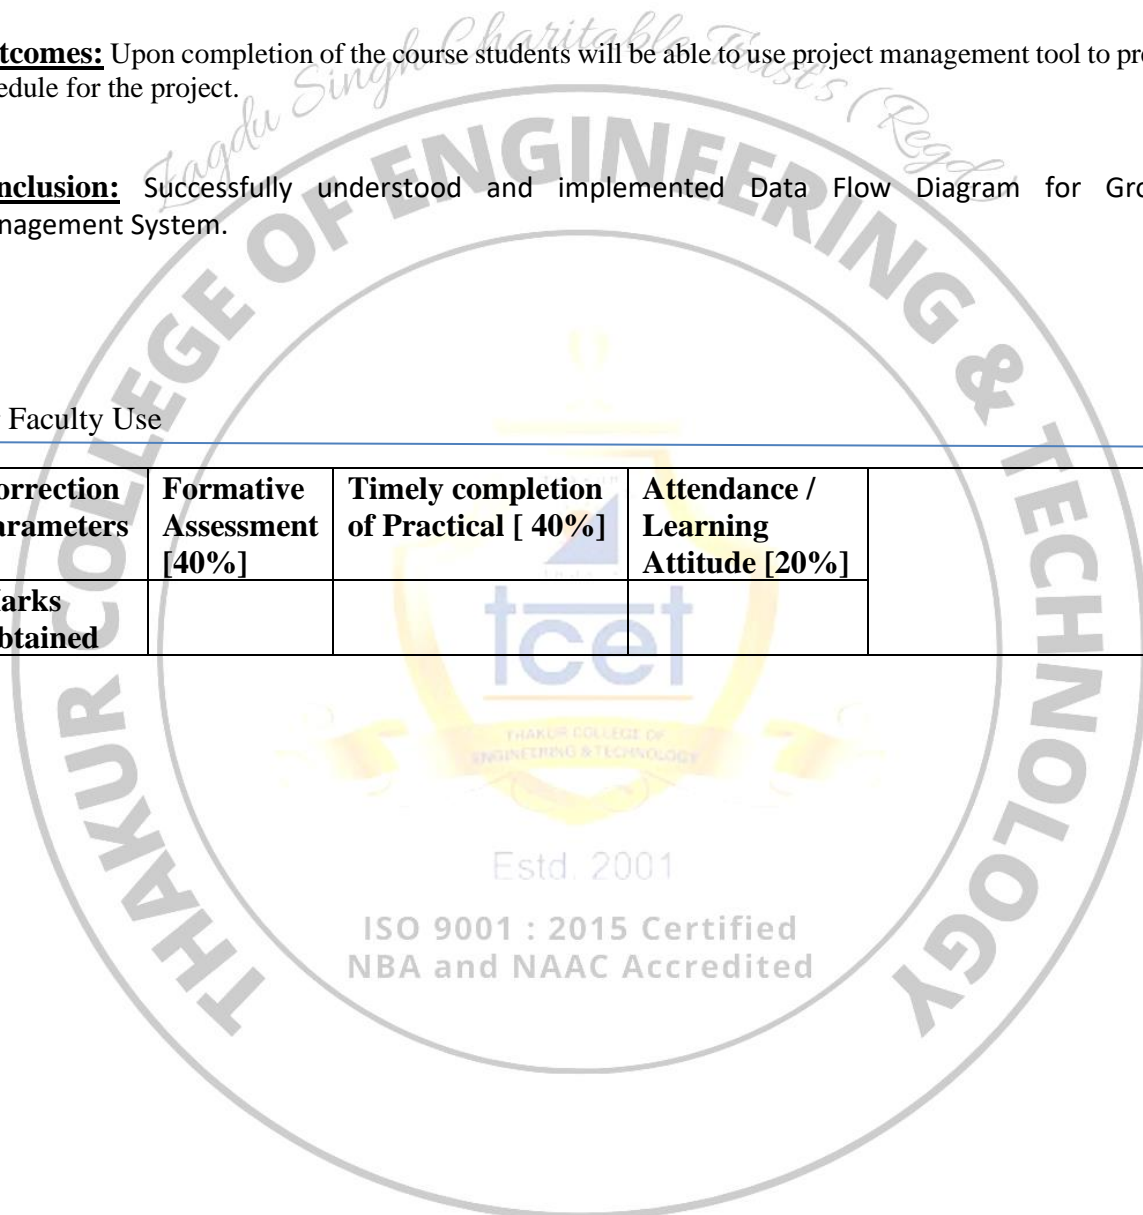

- LO1: List the various activities in the project.
- LO2: Analyze the various activities for schedule.
- LO3: Estimate the time for each activity.
- LO4: Develop a Gantt Chart for the activities.

Outcomes: Upon completion of the course students will be able to use project management tool to prepare schedule for the project.

Conclusion: Successfully understood and implemented Data Flow Diagram for Grocery Management System.

Experiment 8: Change specification and use any SCM Tool to make different versions for the project

Learning Objective: Students will be able to create versions using Github tool

Tools: Github

Theory:

Software configuration management: The traditional software configuration management (SCM) process is looked upon by practitioners as the best solution to handling changes in software projects. It identifies the functional and physical attributes of software at various points in time, and performs systematic control of changes to the identified attributes for the purpose of maintaining software integrity and traceability throughout the software development life cycle.

Software configuration management is a part of software engineering, which focuses mainly on maintaining, tracking and controlling the changes done to the software configuration items.

Configuration management is present in all phase of software development. The configuration items can be all the objects which come as an output of the development process e.g. coding phase produces source code, exes and obj files. The various configuration items can be:

1. Source code,
2. Documents
3. Data used in the programs

In Configuration management, there can be multiple versions created for any configuration item (Source code/ documents). Each version can be identified by unique configuration or an attribute which is associated with each version. E.g. the version number.

Terminologies used in version control

1. SCI – Software configuration items, i.e. the documents and code which will be having version number and saved.
2. Repository- it is the system where all the SCIs will be stored.
3. Check in- to store the tested and qualified source code.
4. Checkout- to get a copy of the stored SCI from the repository.
5. Add – Add to the local repo and keep ready for commit
6. Commit- to save the file in repository and create a version

Advantages

- 1) The versions are stored in the repository; hence they are available as backups.
- 2) Multiple people can work simultaneously on same files/source code, without losing the changes made by other developers
- 3) It is easy to find the files with specifications as a versions are stored with version numbers

GitHub offers all of the distributed revision control and source code management (SCM) functionality of Git as well as adding its own features. Unlike Git, which is strictly a command-line tool, GitHub provides a Web-based graphical interface and desktop as well as mobile integration. It also provides access control and several collaboration features such as bug tracking, feature requests, task management for every project.

Learning Outcomes: Students should have the ability to

LO1: to understand the need of doing configuration management.

LO2: Identify the dissimilarity between version and variant

LO3: provide the knowledge of the benefits of using version control

LO4: To understand the types of version control system

Outcomes: Upon completion of the course students will be able to create versions for the project.

Conclusion: Successfully understood and implemented SCM tools like Github and performed various version control methods.

Viva Questions:

1. What is difference between git and Github?
2. What is version control? Why is it required?
3. What are other tools for version control?
4. What are different types of version control?

For Faculty Use

Correction Parameters	Formative Assessment [40%]	Timely completion of Practical [40%]	Attendance / Learning Attitude [20%]

Experiment 9: Apply the knowledge of test cases for the project using white box testing.

Learning Objective: Students will able to create unit test cases

Tools: Junit

Theory:

Software testing is an investigation conducted to provide stakeholders with information about the quality of the product or service under test. Software testing also provides an objective, independent view of the software to allow the business to appreciate and understand the risks of software implementation.

Unit Testing:

Unit testing focuses on the building blocks of the software system, that is, objects and subsystems. The specific candidates for unit testing are chosen from the object model and the system decomposition. In principle, all the objects developed during the development process should be tested, which is often not feasible because of time and budget constraints. The minimal set of objects to be tested should be the participating objects in the use cases. Subsystems should be tested after each of the objects and classes within that subsystem have been tested individually. Unit testing focuses verification effort on the smallest unit of software design – the software component or module. The unit test is white-box oriented. . In Unit testing the following are tested,

1. The module interface is tested to ensure that information properly flows into and out of the program unit under test.
2. The local data structure is examined to ensure that data stored temporarily maintains its integrity.
3. Boundary conditions are tested to ensure that the module operates properly at boundaries established to limit or restrict processing.
4. All independent paths through the control structure are exercised to ensure that all statements in a module have been executed at least once.
5. And finally, all error handling paths are tested

Write a program to calculate the square of a number in the range 1-100

```
#include <stdio.h>
```

```
int main()
```

```
{
```

```
    int n, res;
```

```
    printf("Enter a number: ");
```

```
    scanf("%d", &n);
```

```
    if (n >= 1 && n <= 100)
```

```
    {
```

```
        res = n * n;
```

```
        printf("\n Square of %d is %d\n", n, res);
```

```
    }
```

```
    else if (n <= 0 || n > 100)
```

```
        printf("Beyond the range");
```

```
    return 0;
```

```
}
```

Sr no	Input	Output
1	-2	Beyond the range
2	0	Beyond the range
3	1	Square of 1 is 1
4	100	Square of 100 is 10000
5	101	Beyond the range
6	4	Square of 4 is 16
7	62	Square of 62 is 3844

Test Cases

Test case 1 : {I1 ,O1}

Test case 2 : {I2 ,O2}

Test case 3 : {I3, O3}

Test case 4 : {I4, O4}

Test case 5 : {I5, O5}

Test case 6 : {I6, O6}

Test case 7 : {I7, O7}

Selenium:

Selenium IDE is an integrated development environment for Selenium tests. It is implemented as a Firefox extension, and allows you to record, edit, and debug tests. Selenium is an open-source tool that automates web browsers. It provides a single interface that lets you write test scripts in programming languages like Ruby, Java, NodeJS, PHP, Perl, Python, and C#, among others.

A browser-driver then executes these scripts on a browser-instance on your device (more on this in a moment).

History of Selenium:

A timeline of major events in the evolution of Selenium from an in-house side-project to an open-source industry standard in browser automation:

2004: Making history in two parts (from Selenium A to B)

- Jason Huggins of ThoughtWorks needs to test his web app's front-end behavior across different browsers.
- He develops a tool that works by injecting JavaScript underneath the webpage, allowing the tester to write code that could 'automate' front-end user interactions.

This became the JavaScript TestRunner.

- Although the JS-injection approach couldn't naturally replicate user interactions (via keystrokes/mouse movements), it was a workaround for the 'same-host origin

policy’, which prohibits external JavaScript code from accessing elements from a domain it didn’t originally reside in. Nonetheless, the tool is positively received by in-house developers and ThoughtWorks’ clients alike.

- The tool is open sourced due to popular demand.
- To eliminate the need for JS-injections, Huggins, along with colleague Paul Hammant, discuss the possibility of a ‘server’ component. This server would act as an HTTP proxy and trick the browser-instance into believing that the test script and the web app under test are from the same source.
- They develop the server component in Java and the original client-side driver (TestRunner) gets ported to Ruby.
- This is the original Selenium. Known as Driven Selenium or Selenium B in the evolution timeline.

2005: Selenium RC (Remote Control)

- Elsewhere (at Bea, specifically), Dan Fabulich and Nelson Sproul begin working on the driver coder. They eventually mold it into a standalone server that bundled MortBay’s Jetty as HTTP proxy.
- This becomes ‘Selenium RC (Remote Control)’ or Selenium 1.0. Before we cut to 2.0, there is another significant development in the form of...

2006: The Selenium IDE

- Shinya Kasatani wraps the Selenium driver code in an IDE module in Firefox browser.
- When it works, he finds that he can run a functional ‘live test’ on a website—interacting with the browser (as a user would); recording/replaying the interactions and debugging as needed.
- Kasatani donates this tool to Selenium project where it becomes known as the Selenium IDE.

2007: The Selenium WebDriver (Selenium 2.0)

- Back at ThoughtWorks, Simon Stewart diligently codes up separate ‘driver’ clients for every popular browser, so they’d all support automation with native browser capabilities.

- It pays off. The project becomes famous as the WebDriver.

2008: Multiply by ‘n’: The Selenium Grid

- At ThoughtWorks, Philippe Hanrigou creates a server which would allow testers to access and run tests on browser instances on any number of remote devices.
- This becomes known as the Grid. Cut to...

2016: Selenium RC gets deprecated and WebDriver becomes standard implementation—aka Selenium 3.0.

2019: WebDriver becomes a W3C standard protocol

Imagine that a manual tester has this scenario: Checking whether the web app’s signup page (www.example.com/signup) validates input strings and registers a user successfully in latest versions of Chrome and Firefox, on Windows 7.

Assume that the signup page has these input fields—username, email address, and password. The tester will get a Windows 7 desktop and follow these steps, consecutively, on latest versions of Chrome and Firefox:

1. Enter the URL in the address bar (www.example.com/signup)
2. Enter an invalid string in each input field (email, username, and password)
3. Check whether the input strings were validated against corresponding regexes and any pre-existing values in the database
4. Enter ‘valid’ strings in each input field; click Sign Up
5. Check whether “Welcome, ‘{‘username’}’” page showed up
6. Check whether the system database created a new userID for ‘{‘username’}’
7. Mark the test ‘passed’ if it did, ‘failed’ if the signup feature broke anywhere during the test.

Types of testing that are commonly automated with Selenium are:

1. Compatibility Testing:

Done by QA professionals/Testers to ensure that the web app meets performance benchmarks on different browser-OS combinations. For example, testing on different devices (mobile and desktop) to ensure that the front-end fits to scale (responsive); testing on different browsers to see if video ads render on the pages as they should.

2. Performance Testing:

Series of tests done by QA professionals/Testers to ensure that the project meets performance benchmarks set by the stakeholders. Tester writes a script that checks whether all elements on homepage load within 2 seconds on different browsers/browser versions.

3. Integration Testing:

Done by developers to verify that units/modules coded separately (that work on their own), also work when put together. Parallel Test Calculator, for instance, has separate layers. UI takes input and business logic calculates the output—then sends it back to UI to display. The tester could verify whether they are able to relay data/output when integrated.

4. System Testing:

aka Black Box testing. Done by Testers/QA professionals with no context of the code or any previously executed tests. Typically centered on a single user workflow. The check out process on a product website, for instance, comprises of: validating user credentials, fetching products from the cart, checking their availability, and validating payment details—before redirecting to the bank website. The tester could write a script to verify that the entire system is functional.

5. End-to-end Testing:

Also done by Testers/QA professionals, typically from the user's point of view. The aim is to verify that all touchpoints on the web app are functional. From the previous example, the tester could write a series of test cases to check that sign-up, product search, checkout, review, bookmark, and all other features function as intended (and fail when

invalid values are entered in input fields).

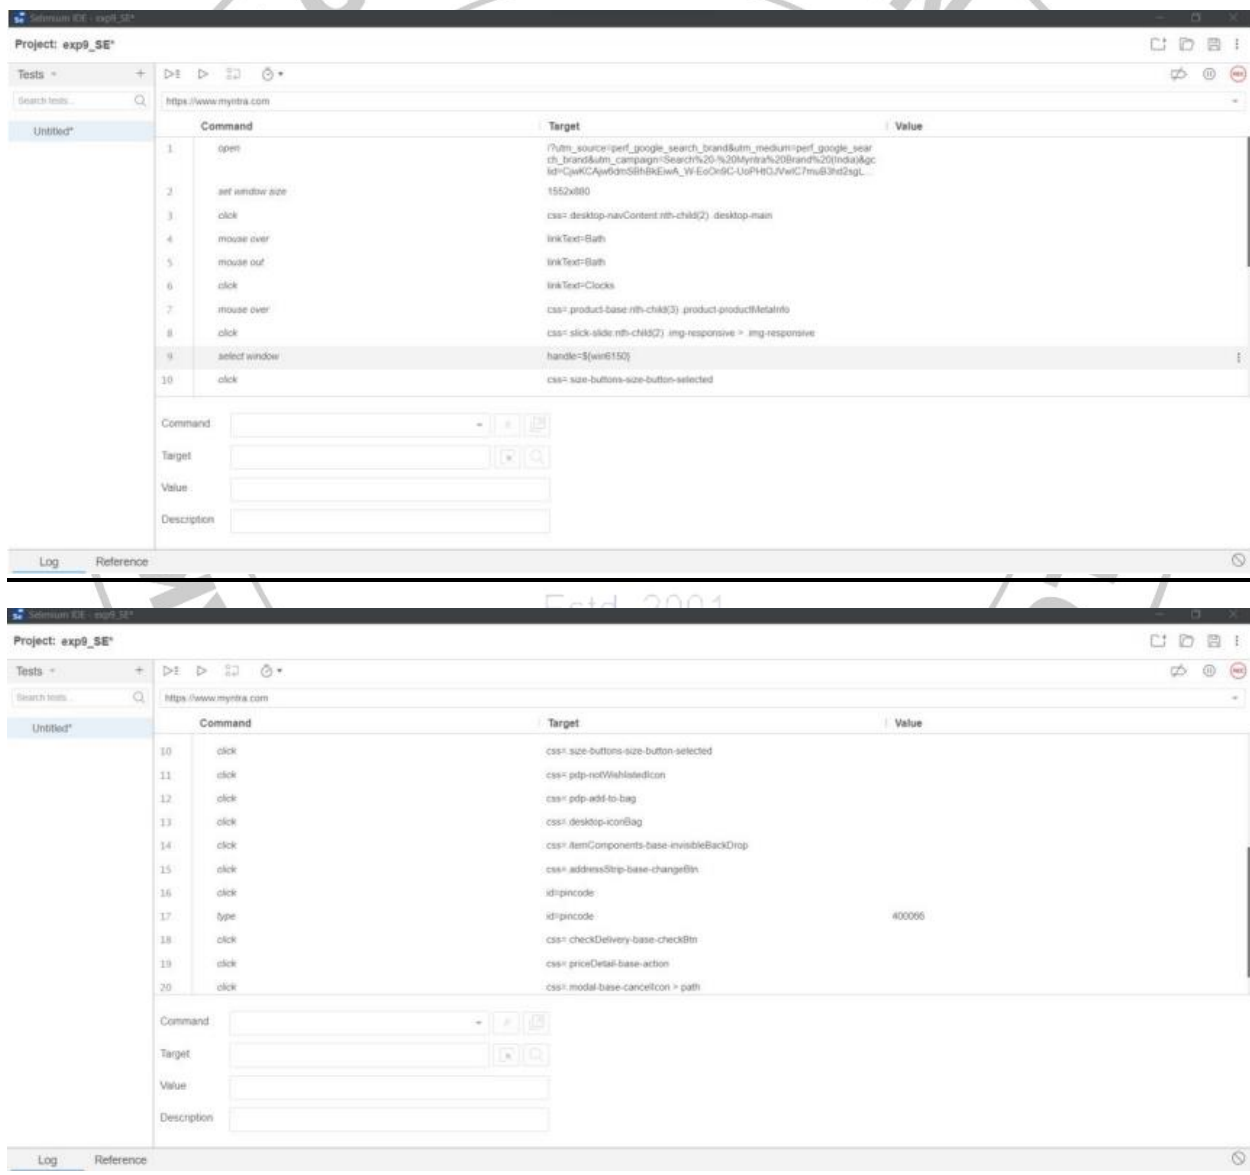

6. Regression Testing:

A series of tests done to ensure that newly built features work with the existing system.

From the same example, say the product website launches a new feature (promotional codes) that automatically apply to eligible items before checkout. The tester could write cases to verify that it doesn't break the rest of the checkout feature.

Well-written test suites can also automate Smoke and Sanity testing with Selenium.

Implementation:

The screenshot displays the Selenium IDE interface for a project named 'exp9_SE'. The browser window shows the URL 'https://www.myntra.com'. The test suite is titled 'Untitled*' and contains two test cases, each with a series of commands and targets.

Command	Target	Value
1. open	/url_source=perf_google_search_brand&utm_medium=perf_google_sear	
2. set window size	1552x800	
3. click	css=desktop-navContent.rth-child(2).desktop-main	
4. mouse over	linkText=Bath	
5. mouse out	linkText=Bath	
6. click	linkText=Clocks	
7. mouse over	css=product-base.rth-child(3).product-productMetaInfo	
8. click	css=slick-slide.rth-child(2).img-responsive > img-responsive	
9. select window	handle=\$win6150	
10. click	css=size-buttons-size-button-selected	
10. click	css=size-buttons-size-button-selected	
11. click	css=size-buttons-size-button-selected	
12. click	css=pdp-notWishListedIcon	
13. click	css=pdp-add-to-bag	
14. click	css=desktop-icorflag	
15. click	css=AlertComponents-base-invisibleBackDrop	
16. click	css=addressStrip-base-changeBtn	
17. type	id=pincode	400095
18. click	css=checkDelivery-base-checkBtn	
19. click	css=priceDetail-base-action	
20. click	css=modal-base-cancelcon > path	

The interface includes a 'Log' tab at the bottom, which is currently empty. The 'Reference' tab is also visible.

Learning Outcomes: Students should have the ability to

LO1: Students will be able to understand Software Testing Concepts and the various Software standards.

LO2: to test a software with the help of Junit

LO3: create test cases

LO4: To understand different tools for testing

Outcomes: Upon completion of the course students will be able to write test cases for the project.

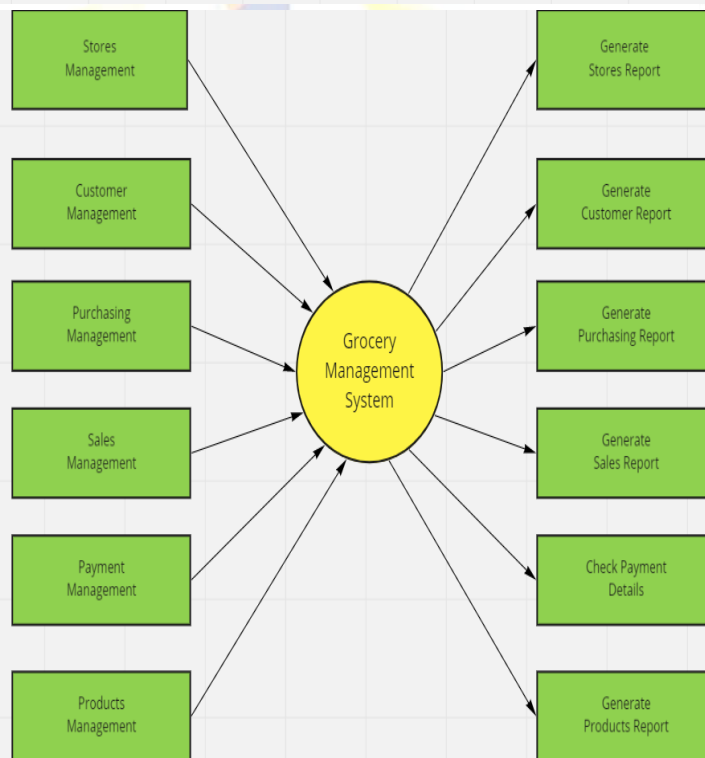

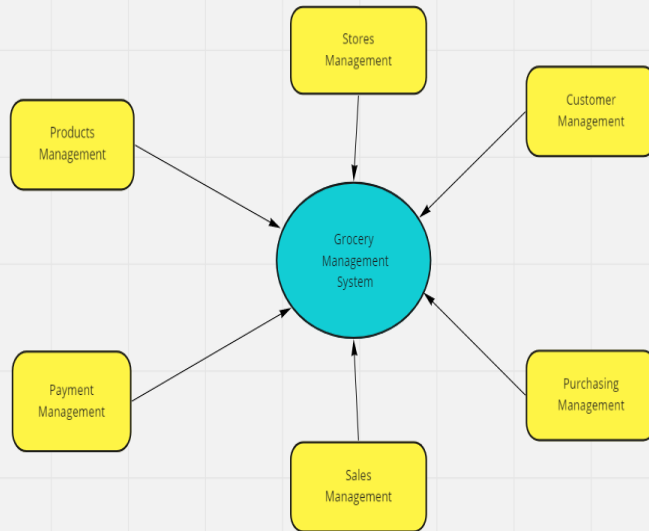

Conclusion: Successfully understood and implemented Software Testing Concepts and the various Software standards and unit testing.

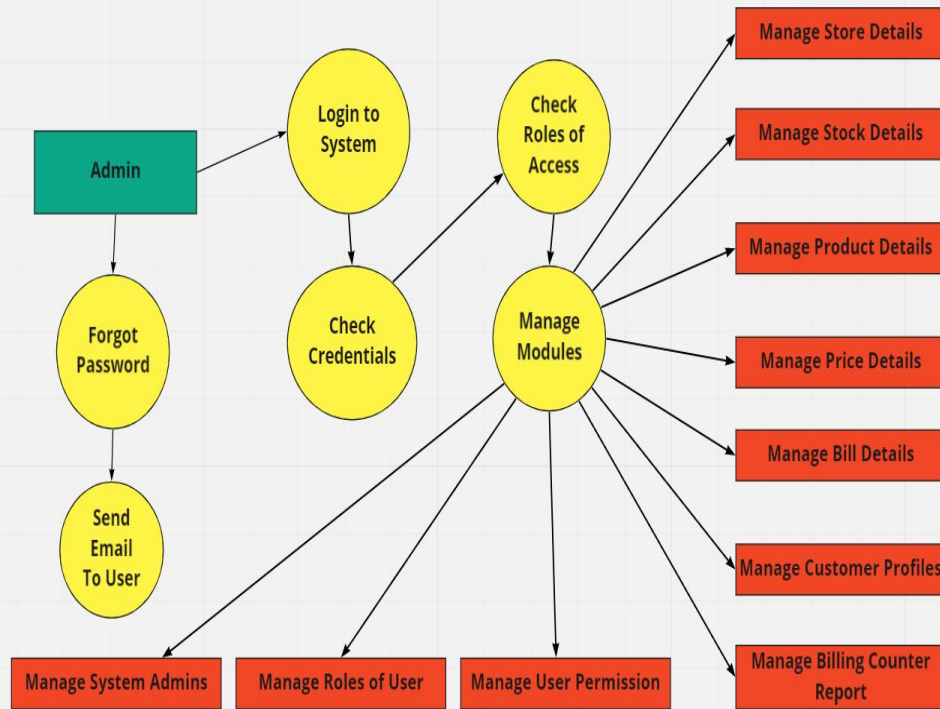

Viva Questions:

1. What is difference between git and Github?
2. What is version control? Why is it required?
3. What are other tools for version control?
4. What are different types of version control?
